

Optimal Control of Multi-Agent Systems with Processing Delays

Mruganka Kashyap*

Laurent Lessard[†]

Abstract

In this article, we consider a cooperative control problem involving dynamically decoupled linear plants. The (output-feedback) controllers for each plant communicate with each other according to a fixed and known network topology, and each transmission incurs a fixed continuous-time processing delay. We provide an explicit closed-form expression for the optimal decentralized controller and its associated cost under these communication constraints and standard linear quadratic Gaussian (LQG) assumptions for the plants and cost function. We find the exact solution without discretizing or otherwise approximating the delays. We also present an implementation of each sub-controller that is efficiently computable, and is composed of standard finite-dimensional linear time-invariant (LTI) and finite impulse response (FIR) components, and has an intuitive observer-regulator architecture reminiscent of the classical separation principle.

1 Introduction

In multi-agent systems such as swarms of unmanned aerial vehicles (UAVs), it may be desirable for agents to cooperate in a decentralized fashion, without receiving instructions from a central coordinating entity. Each agent makes local measurements, performs computations, and may communicate its measurements with a given subset of the other agents, with a time delay. In this paper, we investigate the problem of optimal control under the aforementioned communication constraints.

We model each agent as a continuous-time linear time-invariant (LTI) system. We assume the aggregate dynamics of all agents are described by the state-space equations

$$\begin{bmatrix} \dot{x} \\ z \\ y \end{bmatrix} = \begin{bmatrix} A & B_1 & B_2 \\ C_1 & 0 & D_{12} \\ C_2 & D_{21} & 0 \end{bmatrix} \begin{bmatrix} x \\ w \\ u \end{bmatrix}, \quad (1)$$

where x is the global state, z is the regulated output, y is the measured output, w is the exogenous disturbance, and u is the controlled input. The decoupled nature of the agents imposes a sparsity structure on the plant. Namely, if we partition x , y , w , u each into N pieces corresponding to the N agents, the conformally partitioned state space matrices A , B_1 , B_2 , C_2 , D_{21} are block-diagonal.

[†]L. Lessard is with the Department of Mechanical and Industrial Engineering at Northeastern University, Boston, MA 02115, USA. (e-mail: l.lessard@northeastern.edu).

The regulated output z , however, couples all agents' states and inputs, so in general C_1 and D_{12} will be dense. The matrix transfer function $(w, u) \rightarrow (z, y)$ is a standard four-block plant that takes the form¹

$$\begin{bmatrix} z \\ y \end{bmatrix} = \begin{bmatrix} \mathcal{P}_{11}(s) & \mathcal{P}_{12}(s) \\ \mathcal{P}_{21}(s) & \mathcal{P}_{22}(s) \end{bmatrix} \begin{bmatrix} w \\ u \end{bmatrix}, \quad (2)$$

where \mathcal{P}_{21} and \mathcal{P}_{22} are block-diagonal.

We assume each agent can instantly communicate its measurements with any agent it can reach, according to a (fixed and known) directed graph. However, every transmitted measurement incurs a *processing delay* of τ seconds (for decoding, computation, and storage) before it may be used. We assume τ is fixed and known, as it is determined by the physical capabilities (e.g., underlying hardware and software) of the individual agents rather than external factors. Thus, Agent i 's feedback policy (in the Laplace domain) is of the form²

$$u_i = \mathcal{K}_{ii}(s)y_i + \sum_{j \rightarrow i} e^{-s\tau} \mathcal{K}_{ij}(s)y_j, \quad (3)$$

where the sum is over all agents j for which there is a directed path from j to i in the underlying communication graph.

Given the four-block plant (2), the directed communication graph, and the processing delay τ , we study the problem of finding a structured controller that is internally stabilizing and minimizes the \mathcal{H}_2 norm of the closed-loop map $w \rightarrow z$.

In spite of the non-classical information structure present in this problem, it is known that there is a convex Youla-like parameterization of the set of stabilizing structured controllers, and the associated \mathcal{H}_2 synthesis problem is a convex, albeit infinite-dimensional, optimization problem.

Main contribution. We provide a complete solution to this structured cooperative control problem that is computationally tractable and intuitively understandable. Specifically, the optimal controller can be implemented with a finite memory and transmission bandwidth that does not grow over time. Moreover, the controller implementations at the level of individual agents have observer-compensator separation structures reminiscent of classical \mathcal{H}_2 synthesis theory.

In the remainder of the introduction, we give context to this problem and relate it to works in optimal control, delayed control, and decentralized control. Then, we cover some mathematical preliminaries and give a formal statement of the problem. In Section 3, we give a convex parameterization of all structured sub-optimal controllers, and present the \mathcal{H}_2 -optimal controller for the non-delayed ($\tau = 0$) and delayed ($\tau > 0$) cases. In Section 4, we describe the optimal controller architecture at the level of the individual agents, and give intuitive interpretations of the controller architecture. In Section 5, we present case studies that highlight the trade-offs between processing delay, connectivity of the agents, and optimal control cost. Finally, we conclude in Section 6 and discuss future directions.

¹In a slight abuse of notation, the vectors z , y , w , and u now refer to the Laplace transforms of the corresponding time-domain signals in (1).

²There is no loss of generality in assuming a linear control policy; see Section 1.1 for details.

1.1 Literature review

If we remove the structural constraint (3) and allow each u_i to have an arbitrary causal dependence on all y_j with no delays, the optimal controller is linear and admits an observer–compensator separation structure [30]. This is the classical \mathcal{H}_2 (LQG) synthesis problem, solved for example in [33].

The presence of structural constraints generally leads to an intractable problem [1]. For example, linear compensators can be strictly suboptimal, even under LQG assumptions [29]. Moreover, finding the best *linear* compensator also leads to a non-convex infinite-dimensional optimization problem.

However, not all structural constraints lead to intractable synthesis problems. For LQG problems with *partially nested* (PN) information, there is a linear optimal controller [4]. If the information constraint is *quadratically invariant* (QI) with respect to the plant, the problem of finding the optimal LTI controller can be convexified [22, 23]. The problem considered in this paper is both PN and QI, so there is no loss in assuming a linear policy as we do in (3).

Once the problem is convexified, the optimal controller can be computed exactly using approaches like vectorization [24, 28], or approximated to arbitrary accuracy using Galerkin-style numerical approaches [21, 25]. However, these approaches lead to realizations of the solution that are neither minimal nor easily interpreted. For example, a numerical solution will not reveal a separation structure in the optimal controller, nor will it provide an interpretation of controller states or the signals communicated between agents’ controllers. Indeed, the optimal controller may have a rich structure, reminiscent of the centralized separation principle. Such *explicit solutions* were found for broadcast [13], triangular [15, 27], and dynamically decoupled [5, 7, 8] cases.

The previously mentioned works do not consider time delays. In the presence of delays, we distinguish the cases of discrete vs. continuous-time delays. The delay operator z^{-1} is rational in discrete time. Therefore, the problem may be reduced to the non-delayed case by absorbing each delay into the plant [12]. However, this reduction is not possible in continuous time because the delay operator $e^{-s\tau}$ is now non-rational. A Padé approximation may be used for the delays [31], but this leads to approximation error and a larger state dimension.

Although the inclusion of continuous-time delays renders the state space representation infinite-dimensional, the optimal controller may still have a rich structure. For systems with a *dead-time delay* (the entire control loop is subject to the same delay), a loop-shifting approach using finite impulse response (FIR) blocks can transform the problem into an equivalent delay-free LQG problem with a finite-dimensional LTI plant [16, 20]. A similar idea was used in the discrete-time case to decompose the structure into dead-time and FIR components, which can be optimized separately [11].

The loop-shifting technique can be extended to the *adobe delay* case, where the feedback path contains both a delayed and a non-delayed path [17–19]. The loop-shifting technique was also extended to specific cases like bilateral teleoperation problems that involve two stable plants whose controllers communicate across a delayed channel [2, 9], and haptic interfaces that have two-way communication with a shared virtual environment [10]. Both of these examples are special cases of the information structure (3).

In the present work, we solve a general structured \mathcal{H}_2 synthesis problem with N agents that communicate using a structure of the form (3). We present explicit solutions that show an intuitive observer-compensator structure at the level of each individual sub-controller. Preliminary versions of these results that only considered stable or non-delayed plants were reported in [5, 6].

2 Preliminaries

Transfer matrices Let $\mathbb{C}_\alpha = \{s \in \mathbb{C} \mid \operatorname{Re}(s) > \alpha\}$. A transfer matrix $\mathcal{G}(s)$ is said to be *proper* if there exists an $\alpha > 0$ such that $\sup_{s \in \mathbb{C}_\alpha} \|\mathcal{G}(s)\| < \infty$. We call this set $\mathcal{L}_{\text{prop}}$. The Hilbert space \mathcal{L}_2 consists of analytic functions $\mathcal{F} : \mathbb{C}_0 \rightarrow \mathbb{C}^{m \times n}$ equipped with the inner product $\langle \mathcal{F}, \mathcal{G} \rangle := \frac{1}{2\pi} \int_{\mathbb{R}} \operatorname{tr}(\mathcal{F}(i\omega)^* \mathcal{G}(i\omega)) d\omega$, where the inner product induced norm $\|\mathcal{F}\|_2 := \langle \mathcal{F}, \mathcal{F} \rangle^{1/2}$ is bounded. The set \mathcal{H}_2 is the closed subspace of \mathcal{L}_2 consisting of functions analytic on \mathbb{C}_0 . The set \mathcal{H}_2^\perp is the orthogonal component of \mathcal{H}_2 in \mathcal{L}_2 . The set \mathcal{L}_∞ consists of matrix-valued functions for which $\sup_{\omega \in \mathbb{R}} \|\mathcal{F}(i\omega)\| < \infty$, and \mathcal{H}_∞ is defined analogously to \mathcal{H}_2 .

The state-space notation for transfer functions is

$$\mathcal{G}(s) = \left[\begin{array}{c|c} A & B \\ \hline C & D \end{array} \right] := D + C(sI - A)^{-1}B. \quad (4)$$

A square matrix A is *Hurwitz* if all of its eigenvalues belong to \mathbb{C}_0 . If A is Hurwitz in (4), then $\mathcal{G} \in \mathcal{H}_\infty$. If A is Hurwitz and $D = 0$, then $\mathcal{G} \in \mathcal{H}_2$. The conjugate transpose of \mathcal{G} is

$$\mathcal{G}^\sim(s) = \left[\begin{array}{c|c} -A^\top & C^\top \\ \hline -B^\top & D^\top \end{array} \right].$$

The dynamics (1) and four-block plant \mathcal{P} from (2) satisfy

$$\mathcal{P}(s) := \begin{bmatrix} \mathcal{P}_{11}(s) & \mathcal{P}_{12}(s) \\ \mathcal{P}_{21}(s) & \mathcal{P}_{22}(s) \end{bmatrix} = \left[\begin{array}{c|cc} A & B_1 & B_2 \\ \hline C_1 & 0 & D_{12} \\ C_2 & D_{21} & 0 \end{array} \right]. \quad (5)$$

If we use the feedback policy $u = \mathcal{K}y$, then we can eliminate u and y from (2) to obtain the closed-loop map $w \rightarrow z$, which is given by the lower linear fractional transformation (LFT) defined as $\mathcal{F}_l(\mathcal{P}, \mathcal{K}) := \mathcal{P}_{11} + \mathcal{P}_{12}\mathcal{K}(I - \mathcal{P}_{22}\mathcal{K})^{-1}\mathcal{P}_{21}$. LFTs can be inverted: if $\mathcal{K} = \mathcal{F}_l(\mathcal{J}, \mathcal{Q})$ and \mathcal{J} has a proper inverse, then $\mathcal{Q} = \mathcal{F}_u(\mathcal{J}^{-1}, \mathcal{K})$, where \mathcal{F}_u is the upper linear fractional transformation: $\mathcal{F}_u(\mathcal{P}, \mathcal{K}) := \mathcal{P}_{22} + \mathcal{P}_{21}\mathcal{K}(I - \mathcal{P}_{11}\mathcal{K})^{-1}\mathcal{P}_{12}$.

Block indexing Ordered lists of indices are denoted using $\{\dots\}$. The total number of agents is N and $[N] := \{1, \dots, N\}$. The i^{th} subsystem has state dimension n_i , input dimension m_i , and measurement dimension p_i . The global state dimension is $n := n_1 + \dots + n_N$ and similarly for m and p . The matrix I_k is the identity of size k and $\operatorname{blkd}(\{X_i\})$ is the block-diagonal matrix formed by the blocks $\{X_1, \dots, X_n\}$. The zeros used throughout are matrix or vector zeros and their sizes are dependent on the context.

We write \underline{i} to denote the *descendants* of node i , i.e., the set of nodes j such that there is a directed path from i to j for all $i \in [N]$. By convention, we list i first, and then the remaining indices

alphabetically. The directed path represents the direction of information transfer between the agents. Similarly, \bar{i} denotes the *ancestors* of node i (again listing i first). We also use $\bar{\bar{i}}$ and \underline{i} to denote the *strict* ancestors and descendants, respectively, which excludes i . For example, in Fig. 1, we have $\underline{2} = \{2, 1, 3, 4\}$ and $\bar{2} = \{1, 3\}$.

Fig. 1: Directed graph representing four interconnected systems.

We also use this notation to index matrices. For example, if X is a $N \times N$ block matrix, then $X_{1\bar{2}} = [X_{12} \ X_{11} \ X_{13}]$. We will use specific partitions of the identity matrix throughout: $I_n := \text{blkd}(\{I_{n_i}\})$, and for each agent $i \in [N]$, we define $E_{n_i} := (I_n)_{:i}$ (the i^{th} block column of I_n). We have $n_{\underline{i}} = \sum_{k \in \underline{i}} n_k$ and $n_{\bar{i}} = \sum_{k \in \bar{i}} n_k$, akin to the descendant and ancestor definitions above. The dimensions of $E_{n_{\bar{i}}}$ and $E_{n_{\underline{i}}}$ are determined by the context of use. 1_n is the $n \times 1$ matrix of 1's. Further notations are defined at their points of first use.

2.1 Delay

We follow the notation conventions set in [19]. The *adobe delay* matrix $\Lambda_m^i := \text{blkd}(I_{m_i}, e^{-s\tau} I_{m_{\bar{i}}})$ leaves block i unchanged and imposes a delay of τ on all strict descendants of i . We define $\Gamma : (\mathcal{P}, \Lambda_m^i) \mapsto (\tilde{\mathcal{P}}, \Pi_u, \Pi_b)$ that maps the plant \mathcal{P} in (5) and adobe delay matrix Λ_m^i to a modified plant $\tilde{\mathcal{P}}$ and finite impulse response (FIR) systems Π_u and Π_b . This loop-shifting transformation reported in [17–19] shown in Fig. 2 transforms a loop with adobe input delay into a modified system involving a rational plant $\tilde{\mathcal{P}}$. See Appendix A for details on the definition of Γ .

In this decomposition, $\langle \Delta, \Psi \rangle = 0$ and Ψ is inner, so the closed-loop map satisfies $\|\mathcal{F}_l(\mathcal{P}, \Lambda_m^i \mathcal{K})\|^2 = \|\Delta\|^2 + \|\mathcal{F}_l(\tilde{\mathcal{P}}, \tilde{\mathcal{K}})\|^2$. Thus, we can find the \mathcal{H}_2 -optimal \mathcal{K} by first solving a standard \mathcal{H}_2 problem with $\tilde{\mathcal{P}}$ to obtain $\tilde{\mathcal{K}}$, and then transforming back using $\mathcal{K} = \Pi_u \tilde{\mathcal{K}} (I - \Pi_b \tilde{\mathcal{K}})^{-1}$. This transformation, illustrated in the bottom left panel of Fig. 2, has the form of a *modified Smith predictor*, where the FIR blocks Π_u and Π_b compensate for the effect of the adobe delay in the original loop. See [18, §III.C] for further detail.

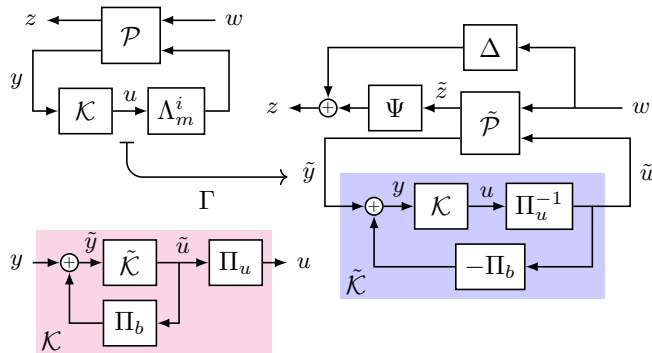

Fig. 2: The loop-shifting approach [17–19] transforms a loop with adobe input delay (top left) into a modified system involving a rational plant $\tilde{\mathcal{P}}$ and FIR blocks Π_u and Π_b (right). This transformation Γ is defined in Appendix A. We can recover \mathcal{K} from $\tilde{\mathcal{K}}$ via the inverse transformation (bottom left).

2.2 Problem statement

Consider a four-block plant (5) representing the aggregated dynamics of N agents as described in Section 1, which we label using indices $i \in [N]$. Suppose $x \in \mathbb{R}^n$, $u \in \mathbb{R}^m$, and $y \in \mathbb{R}^p$, partitioned conformally with the N subsystems as $n = n_1 + \dots + n_N$ and similarly for m and p .

Consider a directed graph on the nodes $[N]$, and let \mathcal{S}_τ be the set of compensators of the form (3). For example, for the directed graph of Fig. 1, we would have

$$\mathcal{S}_\tau = \left\{ \left[\begin{array}{cccc} \mathcal{K}_{11} & e^{-s\tau}\mathcal{K}_{12} & e^{-s\tau}\mathcal{K}_{13} & 0 \\ e^{-s\tau}\mathcal{K}_{21} & \mathcal{K}_{22} & e^{-s\tau}\mathcal{K}_{23} & 0 \\ e^{-s\tau}\mathcal{K}_{31} & e^{-s\tau}\mathcal{K}_{32} & \mathcal{K}_{33} & 0 \\ e^{-s\tau}\mathcal{K}_{41} & e^{-s\tau}\mathcal{K}_{42} & e^{-s\tau}\mathcal{K}_{43} & \mathcal{K}_{44} \end{array} \right] \middle| \mathcal{K}_{ij} \in \mathcal{L}_{\text{prop}} \right\}.$$

So each agent may use its local measurements with no delay, and measurements from its ancestors with a delay of τ . An output-feedback policy $u = \mathcal{K}y$ (internally) *stabilizes* \mathcal{P} if

$$\begin{bmatrix} I & -\mathcal{P}_{22} \\ -\mathcal{K} & I \end{bmatrix}^{-1} \in \mathcal{H}_\infty.$$

For further background on stabilization, we refer the reader to [3, 33]. We consider the problem of finding a structured controller that is stabilizing and minimizes the \mathcal{H}_2 norm of the closed-loop map. Specifically, we seek to

$$\begin{aligned} & \underset{\mathcal{K}}{\text{minimize}} && \|\mathcal{F}_l(\mathcal{P}, \mathcal{K})\|_2^2 \\ & \text{subject to} && \mathcal{K} \in \mathcal{S}_\tau \text{ and } \mathcal{K} \text{ stabilizes } \mathcal{P}. \end{aligned} \tag{6}$$

Technical assumptions Matrices (A, B, C, D) satisfy the *Riccati assumptions* [7, 19] if:

- R1. $D^\top D \succ 0$.
- R2. (A, B) is stabilizable.
- R3. $\begin{bmatrix} A - j\omega I & B \\ C & D \end{bmatrix}$ has full column rank for all $\omega \in \mathbb{R}$.

If the Riccati assumptions hold, there is a unique stabilizing solution for the corresponding algebraic Riccati equation. We write this as $(X, F) = \text{Ric}(A, B, C, D)$. Thus $X \succ 0$ satisfies

$$A^\top X + XA + C^\top C - (XB + C^\top D)(D^\top D)^{-1}(B^\top X + D^\top C) = 0,$$

with $A + BF$ Hurwitz and $F := -(D^\top D)^{-1}(B^\top X + D^\top C)$.

Assumption 1 (System assumptions) For the N interacting agents, the Riccati assumptions hold for (A, B_2, C_1, D_{12}) and for $(A_{ii}^\top, C_{2ii}^\top, B_{1ii}^\top, D_{21ii}^\top)$ for all $i \in [N]$.

Assumption 1 ensures the necessary condition that the centralized LQR problem and estimation problems for the individual agents are non-degenerate. We make no assumptions regarding the open-loop stability of \mathcal{P} .

Riccati equations The algebraic Riccati equations (AREs) corresponding to the centralized LQR and Kalman filtering problem are given by

$$(X_{\text{cen}}, F_{\text{cen}}) := \text{Ric}(A, B_2, C_1, D_{12}), \quad (7a)$$

$$(Y_{\text{cen}}, L_{\text{cen}}^\top) := \text{Ric}(A^\top, C_2^\top, B_1^\top, D_{21}^\top). \quad (7b)$$

Consider controlling the descendants of Agent i using only measurements y_i . The associated four-block plant is

$$\mathcal{P}_i := \begin{bmatrix} \mathcal{P}_{11:i} & \mathcal{P}_{12:i} \\ \mathcal{P}_{21:ii} & \mathcal{P}_{22:ii} \end{bmatrix} := \left[\begin{array}{c|cc} A_{ii} & B_{1ii} & B_{2ii} \\ \hline C_{1:i} & 0 & D_{12:i} \\ C_{2:ii} & D_{21:ii} & 0 \end{array} \right], \quad (8)$$

and we define the corresponding ARE solutions as

$$(X^i, F^i) := \text{Ric}(A_{ii}, B_{2ii}, C_{1:i}, D_{12:i}), \quad (9a)$$

$$(Y^i, L^i{}^\top) := \text{Ric}(A_{ii}^\top, C_{2:ii}^\top, B_{1:ii}^\top, D_{21:ii}^\top). \quad (9b)$$

Note that the block-diagonal structure of the estimation subproblems implies $Y_{\text{cen}} = \text{blkd}(\{Y^i\})$ and $L_{\text{cen}} = \text{blkd}(\{L^i\})$. If we apply the loop-shifting transformation Γ described in Section 2.1 and Fig. 2, we obtain the modified plant

$$\tilde{\mathcal{P}}_i := \begin{bmatrix} \tilde{\mathcal{P}}_{11:i} & \tilde{\mathcal{P}}_{12:i} \\ \tilde{\mathcal{P}}_{21:ii} & \tilde{\mathcal{P}}_{22:ii} \end{bmatrix} := \left[\begin{array}{c|cc} A_{ii} & B_{1ii} & \tilde{B}_{2ii} \\ \hline \tilde{C}_{1:i} & 0 & D_{12:i} \\ C_{2:ii} & D_{21:ii} & 0 \end{array} \right].$$

This modified plant has the same estimation ARE as in (9b), but a new control ARE, which we denote

$$(\tilde{X}^i, \tilde{F}^i) := \text{Ric}(A_{ii}, \tilde{B}_{2ii}, \tilde{C}_{1:i}, D_{12:i}), \quad (10)$$

3 Optimal Controller

We now present our solution to the structured optimal control problem described in Section 2.2. We begin with a convex parameterization of all structured stabilizing controllers.

3.1 Parameterization of stabilizing controllers

This parameterization is similar to the familiar state-space parameterization of all stabilizing controllers [3, 33], but with an additional constraint on the parameter \mathcal{Q} to enforce the required controller structure.

Lemma 2 *Consider a general instance of the structured optimal control problem described in Section 2.2 with \mathcal{P} given by (5) and suppose Assumption 1 holds. Pick F_d and L_d block-diagonal such that $A + B_2 F_d$ and $A + L_d C_2$ are Hurwitz. The following are equivalent:*

- (i) $\mathcal{K} \in \mathcal{S}_\tau$ and \mathcal{K} stabilizes \mathcal{P} .

(ii) $\mathcal{K} = \mathcal{F}_l(\mathcal{J}, \mathcal{Q})$ for some $\mathcal{Q} \in \mathcal{H}_\infty \cap \mathcal{S}_\tau$, where

$$\mathcal{J} := \left[\begin{array}{c|cc} A + B_2 F_d + L_d C_2 & -L_d & B_2 \\ \hline F_d & 0 & I \\ -C_2 & I & 0 \end{array} \right]. \quad (11)$$

Proof. A similar approach was used in [14, Thm. 11] to parameterize the set of stabilizing controllers when $\mathcal{K} \in \mathcal{S}_0$ (no delays). In the absence of the constraint $\mathcal{K} \in \mathcal{S}_\tau$, the set of stabilizing controllers is given by $\{\mathcal{F}_l(\mathcal{J}, \mathcal{Q}) \mid \mathcal{Q} \in \mathcal{H}_\infty\}$ [33, Thm. 12.8]. It remains to show that $\mathcal{K} \in \mathcal{S}_\tau$ if and only if $\mathcal{Q} \in \mathcal{S}_\tau$. It is easy to check that \mathcal{S}_τ is closed under addition, multiplication, and inversion (whenever the matrix partitions are compatible). Therefore, \mathcal{S}_τ is an *algebra*. Expanding the definition of the lower LFT, we have

$$\mathcal{K} = \mathcal{J}_{11} + \mathcal{J}_{12} \mathcal{Q} (I - \mathcal{J}_{22} \mathcal{Q})^{-1} \mathcal{J}_{21}. \quad (12)$$

The matrices A, B_2, C_2, F_d, L_d are block-diagonal, so \mathcal{J}_{ij} is block-diagonal and therefore $\mathcal{J}_{ij} \in \mathcal{S}_\tau$. Since \mathcal{S}_τ is an algebra, it follows from (12) that $\mathcal{Q} \in \mathcal{S}_\tau \implies \mathcal{K} \in \mathcal{S}_\tau$. Applying the inversion property of LFTs, we have $\mathcal{Q} = \mathcal{F}_u(\mathcal{J}^{-1}, \mathcal{K})$. Now

$$\mathcal{J}^{-1} = \left[\begin{array}{c|cc} A & B_2 & -L_d \\ \hline C_2 & 0 & I \\ -F_d & I & 0 \end{array} \right],$$

so we can apply a similar argument to the above to conclude that $(\mathcal{J}^{-1})_{ij} \in \mathcal{S}_\tau$ and $\mathcal{K} \in \mathcal{S}_\tau \implies \mathcal{Q} \in \mathcal{S}_\tau$. \blacksquare

We refer to \mathcal{Q} in Lemma 2 as the *Youla parameter*, due to its similar role as in the classical Youla parameterization [32].

Remark 3 *Although the problem we consider is quadratically invariant (QI), the existing approaches for convexifying a general QI problem [23] or even a QI problem involving sparsity and delays [22] require strong assumptions, such as \mathcal{P}_{22} being stable or strongly stabilizable. Due to the particular delay structure of our problem, the parameterization presented in Lemma 2 does not require any special assumptions and holds for arbitrary (possibly unstable) \mathcal{P} .*

Remark 4 *In the special case where A is Hurwitz (so \mathcal{P} is stable), we can substitute $F_d = 0$ and $L_d = 0$ in (11) to obtain a simpler parameterization of stabilizing controllers.*

Using the parameterization of Lemma 2, we can rewrite the synthesis problem (6) in terms of the Youla parameter \mathcal{Q} . After simplification, we obtain the convex optimization problem

$$\begin{aligned} & \underset{\mathcal{Q}}{\text{minimize}} && \|\mathcal{T}_{11} + \mathcal{T}_{12} \mathcal{Q} \mathcal{T}_{21}\|_2^2 \\ & \text{subject to} && \mathcal{Q} \in \mathcal{H}_2 \cap \mathcal{S}_\tau. \end{aligned} \quad (13)$$

where $\mathcal{T} = \begin{bmatrix} \mathcal{T}_{11} & \mathcal{T}_{12} \\ \mathcal{T}_{21} & 0 \end{bmatrix}$

$$= \left[\begin{array}{cc|cc} A + B_2 F_d & -B_2 F_d & B_1 & B_2 \\ 0 & A + L_d C_2 & B_1 + L_d D_{21} & 0 \\ \hline C_1 + D_{12} F_d & -D_{12} F_d & 0 & D_{12} \\ 0 & C_2 & D_{21} & 0 \end{array} \right]. \quad (14)$$

We replaced $\mathcal{Q} \in \mathcal{H}_\infty$ by $\mathcal{Q} \in \mathcal{H}_2$ in (13) because the closed-loop map must be strictly proper in order to have a finite \mathcal{H}_2 norm. Since \mathcal{T}_{11} is strictly proper, this forces \mathcal{Q} to be strictly proper as well, and hence $\mathcal{Q} \in \mathcal{H}_2$.

Remark 5 *The convex problem (13)–(14) is similar to its unstructured counterpart [33, Thm. 12.16], except we have the additional constraint $\mathcal{Q} \in \mathcal{S}_\tau$ on the Youla parameter.*

Remark 6 *For simplicity, we use $L := L_{\text{cen}} = L_d = \text{blkd}(\{L^i\})$ throughout the rest of the paper.*

3.2 Optimal controller without delays

When there are no processing delays ($\tau = 0$), the optimal structured controller is rational. We now provide an explicit state-space formula for this optimal \mathcal{K} .

Theorem 7 *Consider a general instance of the structured optimal control problem described in Section 2.2 and suppose Assumption 1 holds. Choose a block-diagonal F_d such that $A + B_2 F_d$ is Hurwitz. A realization of the \mathcal{Q}_{opt} that solves (13) in the case $\tau = 0$ is given by*

$$\mathcal{Q}_{\text{opt}} = \left[\begin{array}{c|c} \bar{A} + \bar{B}\bar{F} & -\bar{L}\bar{\mathbf{1}}_p \\ \hline \bar{\mathbf{1}}_m^\top (\bar{F} - \bar{F}_d) & 0 \end{array} \right], \quad (15)$$

and the corresponding \mathcal{K}_{opt} that solves (6) is given by

$$\mathcal{K}_{\text{opt}} = \left[\begin{array}{c|c} \bar{A} + \bar{B}\bar{F} + \bar{L}\bar{C}\bar{\mathbf{1}}_n\bar{\mathbf{1}}_n^\top & -\bar{L}\bar{\mathbf{1}}_p \\ \hline \bar{\mathbf{1}}_m^\top \bar{F} & 0 \end{array} \right]. \quad (16)$$

In (15)–(16), we defined the new symbols

$$\begin{aligned} \bar{A} &:= I_N \otimes A, & \bar{B} &:= I_N \otimes B_2, & \bar{C} &:= I_N \otimes C_2, & \bar{F}_d &:= I_N \otimes F_d, \\ \bar{\mathbf{1}}_n &:= \mathbf{1}_N \otimes I_n, & \bar{\mathbf{1}}_m &:= \mathbf{1}_N \otimes I_m, & \bar{\mathbf{1}}_p &:= \mathbf{1}_N \otimes I_p. \end{aligned}$$

Matrices \bar{L} and \bar{F} are block-diagonal concatenations of zero-padded LQR and Kalman gains for each agent. Specifically, $\bar{F} := \text{blkd}(\{E_{m_i} F^i E_{n_i}^\top\})$ and $\bar{L} := \text{blkd}(\{E_{n_i} L^i E_{p_i}^\top\})$ for all $i \in [N]$, where F^i and L^i are defined in (9).

Proof. See Appendix C. ■

Remark 8 *The optimal controller (16) can also be expressed explicitly in terms of the adjacency matrix; see for example [5, 26]. We opt for the realization (16) as this expression generalizes more readily to the case with delays.*

Remark 9 *Since agents can act as relays, any cycles present in the communication graph can be collapsed and the associated nodes can be aggregated. For example, the graph of Fig. 1 would become the two-node graph $\{1, 2, 3\} \rightarrow \{4\}$. So in the delay-free setting, there is no loss of generality in assuming the communication graph is acyclic.*

Remark 10 *Although the optimal \mathcal{Q}_{opt} (15) and associated \mathcal{J} (11) depend explicitly on F_d , the optimal \mathcal{K}_{opt} (16) does not.*

3.3 Optimal controller with delays

In this section, we generalize Theorem 7 to include arbitrary processing delays. To this end, we introduce a slight abuse of notation to aid in representing non-rational transfer functions. We generalize the notation of (4) to allow for A, B, C, D that depend on s . So we write:

$$\left[\begin{array}{c|c} A(s) & B(s) \\ \hline C(s) & D(s) \end{array} \right] := D(s) + C(s)(sI - A(s))^{-1}B(s).$$

Theorem 11 *Consider the setting of Theorem 7. The transfer function of $\mathcal{Q}_{\text{opt}} \in \mathcal{H}_2 \cap \mathcal{S}_\tau$ that solves (13) for any $\tau \geq 0$ is*

$$\mathcal{Q}_{\text{opt}} = \left[\begin{array}{cc|c} \bar{A} + \bar{L}\bar{C} & \tilde{B}\tilde{F} - \bar{L}\bar{\Pi}_b\tilde{F} - \bar{B}\bar{\Pi}_u\tilde{F} & 0 \\ \bar{L}\bar{C} & \bar{A} + \tilde{B}\tilde{F} - \bar{L}\bar{\Pi}_b\tilde{F} & -\bar{L}\bar{\mathbf{1}}_p \\ \hline \bar{\mathbf{1}}_m^\top \bar{\Lambda}_m \bar{F}_d & \bar{\mathbf{1}}_m^\top \bar{\Lambda}_m (\bar{\Pi}_u \tilde{F} - \bar{F}_d) & 0 \end{array} \right] \quad (17)$$

and the corresponding \mathcal{K}_{opt} that solves (6) is given by

$$\mathcal{K}_{\text{opt}} = \left[\begin{array}{c|c} \bar{A} + \tilde{B}\tilde{F} + \bar{L}\bar{C}\bar{\mathbf{1}}_n\bar{\mathbf{1}}_n^\top\bar{\Lambda}_n - \bar{L}\bar{\Pi}_b\tilde{F} & -\bar{L}\bar{\mathbf{1}}_p \\ \hline \bar{\mathbf{1}}_m^\top \bar{\Lambda}_m \bar{\Pi}_u \tilde{F} & 0 \end{array} \right], \quad (18)$$

where $\bar{A}, \bar{L}, \bar{F}_d, \bar{\mathbf{1}}_n, \bar{\mathbf{1}}_m, \bar{\mathbf{1}}_p$, are defined in Theorem 7. The remainder of the symbols are defined as follows. We apply the loop-shifting transformation $(\tilde{\mathcal{P}}_i, \tilde{\Pi}_{u_i}, \tilde{\Pi}_{b_i}) = \Gamma(\mathcal{P}_i, \Lambda_m^i)$, where $\mathcal{P}_i, \tilde{\mathcal{P}}_i, \tilde{F}^i$ are defined in Section 2.2, and

$$\begin{aligned} \tilde{F} &:= \text{blkd}(\{E_{m_i}\tilde{F}^i E_{n_i}^\top\}), & \bar{\Pi}_b &:= \text{blkd}(\{E_{p_i}\tilde{\Pi}_{b_i} E_{m_i}^\top\}), \\ \tilde{B} &:= \text{blkd}(\{E_{n_i}\tilde{B}_{2_{ii}} E_{m_i}^\top\}), & \bar{\Pi}_u &:= \text{blkd}(\{E_{m_i}\tilde{\Pi}_{u_i} E_{m_i}^\top\}), \\ \bar{\Lambda}_k &:= \text{blkd}(\{E_{k_i}\Lambda_k^i E_{k_i}^\top\}), & & \text{for } k \in \{m, n\}. \end{aligned}$$

Proof. See Appendix D. ■

The transfer matrices \mathcal{Q}_{opt} in (17) and \mathcal{K}_{opt} in (18) are not rational, due to the presence of the FIR blocks $\bar{\Pi}_u, \bar{\Pi}_b$, and delay block $\bar{\Lambda}$. Consequently, we cannot write standard state-space realizations as in Theorem 7. When $\tau = 0$, we have $\bar{\Pi}_u = I, \bar{\Pi}_b = 0, \bar{\Lambda}_m = I, \tilde{F} = \bar{F}$, and $\tilde{B} = \bar{B}$, and we recover the results of Theorem 7.

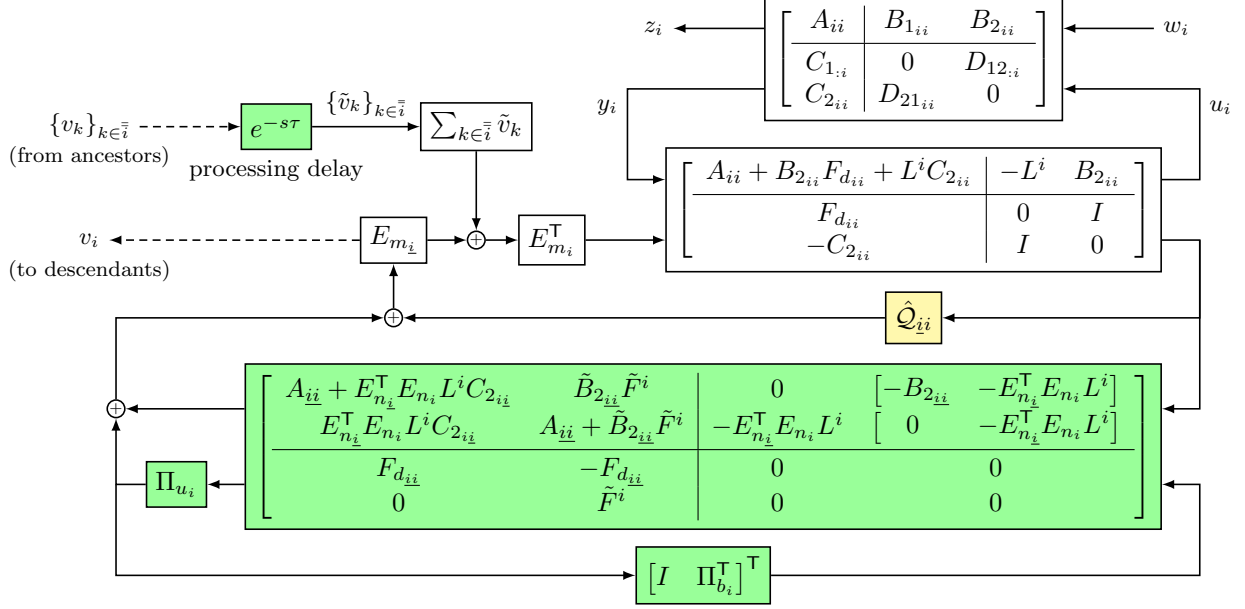

Fig. 3: Agent-level implementation of all structured stabilizing controllers, parameterized by $\hat{Q} \in \mathcal{H}_2 \cap \mathcal{S}_0$. Here, F_d is any block-diagonal matrix such that $A_{ii} + B_{2i}F_{dii}$ is Hurwitz. The \mathcal{H}_2 -optimal controller is achieved when $\hat{Q} = 0$, and results in the simplified diagram of Fig. 4. The blocks that depend on the processing delay τ are colored in green. All symbols are defined in Theorem 12.

4 Agent-level controllers

The optimal controllers presented in Theorems 7 and 11 are generally not minimal. For example, \mathcal{K}_{opt} in (16) has a state dimension of Nn , which means a copy of the global plant state for each agent. However, if we extract the part of \mathcal{K}_{opt} associated with a particular agent, there is a dramatic reduction in state dimension. So in a distributed implementation of this controller, each agent would only need to store a small subset of the controller's state.

Our next result presents minimal realizations for these *agent-level* controllers and characterizes the information each agent should store and communicate with their neighbors. We find that Agent i simulates its descendants' dynamics, and so has dimension n_i , which is much smaller than the dimension Nn of the aggregate optimal controller from Theorem 7.

Theorem 12 *Consider the setting of Theorem 7 with $\tau \geq 0$. The agent-level implementation of all structured stabilizing controllers, parameterized by $\hat{Q} \in \mathcal{H}_2 \cap \mathcal{S}_0$, is shown in Fig. 3. Here, the optimal controller is achieved when $\hat{Q} = 0$. In this case, we obtain the simpler structure of Fig. 4. All symbols used are defined in Theorems 7 and 11.*

Proof. See Appendix E. ■

4.1 Interpretation of optimal controller

Fig. 3 shows that Agent i transmits the same signal v_i to each of its strict descendants. When an agent receives the signals $\{v_k\}$ from its strict ancestors $k \in \bar{i}$, it selectively extracts and sums

Fig. 4: Agent-level implementation of the \mathcal{H}_2 -optimal controller with processing delays. This is the result of setting $\hat{Q} = 0$ in Fig. 3. The blocks that depend on the processing delay τ are colored in green. All symbols are defined in Theorem 12.

together certain components of the signals. To implement the optimal controller, each agent only needs to know the dynamics and topology of its descendants.

If the network has the additional property that there is at most one directed path connecting any two nodes³, then the communication scheme can be further simplified. Since Agent i 's decision u_i is a sum of terms from all ancestors, but each ancestor has exactly one path that leads to i , the optimal controller can be implemented by transmitting all information to *immediate descendants only* and performing recursive summations. This scheme is illustrated for a four-node chain graph in Fig. 5.

Fig. 5: Four-agent chain graph with standard broadcast (top) and efficient immediate-neighbor implementation (bottom), which is possible because this graph is a multitree.

Remark 13 The agent-level controller from Fig. 4 can be represented as the combination of an observer with transfer matrix $\mathcal{T}_{\underline{ii}} := (sI - A_{\underline{ii}} - E_{n_i}^T E_{n_i} L^i C_{2:ii})^{-1}$, and a regulator with an LQR gain \tilde{F}^i in Fig. 6. This yields a separation structure reminiscent of standard LQG theory [33].

Remark 14 Compared to the architecture proposed in [6, Fig. 4], the agent-level optimal controller in Fig. 4 is more efficient because each agent transmits a single vector v_i to its descendants, instead of two.

³Also known as a *multitree* or a *diamond-free poset*.

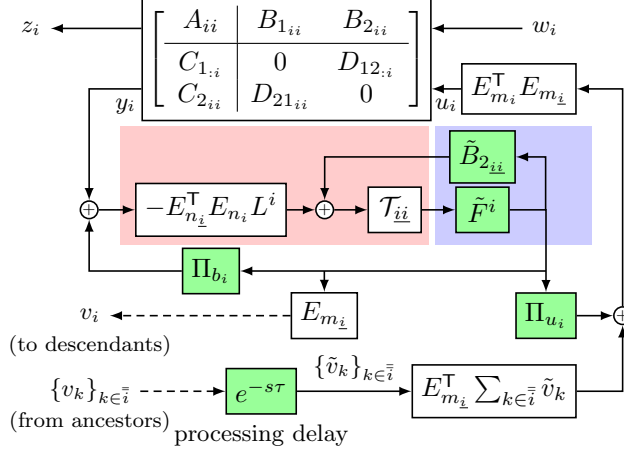

Fig. 6: Agent-level implementation of the \mathcal{H}_2 -optimal controller with processing delays, featuring an observer (red) and regulator (blue) separation structure. Here $\mathcal{T}_{ii} := (sI - A_{ii} - E_{n_i}^T E_{n_i} L^i C_{2ii})^{-1}$ is the transfer matrix of the observer dynamics.

Remark 15 The controller in Fig. 4 has the form of a feed-forward Smith predictor, similar to Fig. 2 (bottom left). The FIR block Π_{u_i} compensates for the effect of adobe delay. Similarly, the FIR block Π_{b_i} resembles the internal feedback in traditional dead-time controllers.

5 Characterizing the cost

In this section, we characterize the cost of any structured stabilizing controller. The cost is defined as $J := \|\mathcal{F}_l(\mathcal{P}, \mathcal{K})\|_2^2 = \|\mathcal{T}_{11} + \mathcal{T}_{12} \mathcal{Q} \mathcal{T}_{21}\|_2^2$, where \mathcal{K} is feasible for (6) or equivalently, $\mathcal{Q} = \mathcal{F}_u(\mathcal{J}^{-1}, \mathcal{K})$ is feasible for (13) (see Lemma 2). We show how to interpret the cost in different ways, and how to compute it efficiently. We illustrate our result using an example with $N = 4$ agents.

Theorem 16 Consider the setting of Theorem 7. The optimal (minimal) costs for the cases: a fully connected graph with no delays, a decentralized graph with no delays, a fully connected graph with delays, and a decentralized graph with delays are:

$$J_{\text{cen}} = \text{tr}(Y_{\text{cen}} C_1^T C_1) + \text{tr}(X_{\text{cen}} L D_{21} D_{21}^T L^T), \quad (19a)$$

$$J_{\text{dec}} = \text{tr}(Y_{\text{cen}} C_1^T C_1) + \text{tr}(X_{\text{dec}} L D_{21} D_{21}^T L^T), \quad (19b)$$

$$J_{\text{del}} = \text{tr}(Y_{\text{cen}} C_1^T C_1) + \text{tr}(X_{\text{del}} L D_{21} D_{21}^T L^T), \quad (19c)$$

$$J_{\text{dec,del}} = \text{tr}(Y_{\text{cen}} C_1^T C_1) + \text{tr}(X_{\text{dec,del}} L D_{21} D_{21}^T L^T), \quad (19d)$$

respectively. If a feasible but sub-optimal \mathcal{Q} is used in any of the above cases, write $\mathcal{Q}_\Delta := \mathcal{Q} - \mathcal{Q}_{\text{opt}}$. The cost of this sub-optimal \mathcal{Q} is found by adding $J_{\mathcal{Q}} := \|\mathcal{T}_{12} \mathcal{Q}_\Delta D_{21}\|_2^2$ to (19a)–(19d). The various symbols are defined as

$$\begin{aligned} X_{\text{dec}} &:= \text{blkd}(\{X^i(1, 1)\}), & X_{\text{del}} &:= \text{blkd}(\{\Xi_{c_\tau}^i(1, 1)\}), \\ X_{\text{dec,del}} &:= \text{blkd}(\{\Xi_\tau^i(1, 1)\}), & & \text{and satisfy} \end{aligned}$$

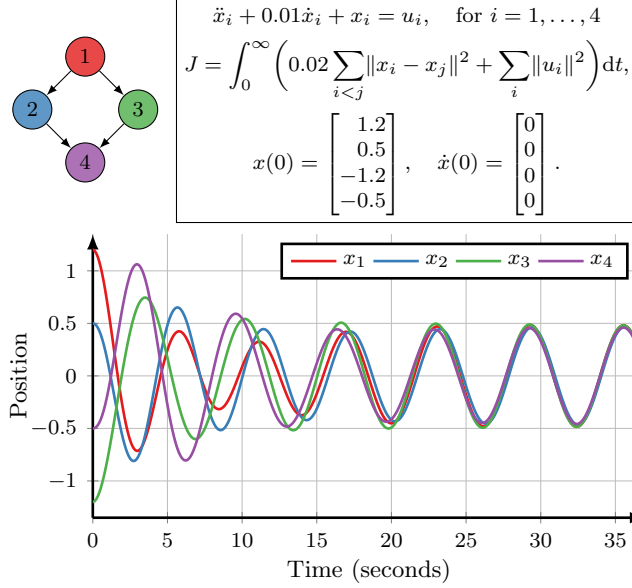

Fig. 7: Synchronization example of a 4-agent system with no processing delay and state feedback (LQR).

$$\text{blkd}(\{X_{\text{cen}}(i, i)\}) \leq X_{\text{dec}} \leq X_{\text{dec,del}}, \quad (20a)$$

$$\text{blkd}(\{X_{\text{cen}}(i, i)\}) \leq X_{\text{del}} \leq X_{\text{dec,del}}. \quad (20b)$$

$X_{\text{cen}}, Y_{\text{cen}}, F_{\text{cen}}$, and L are defined in Section 2.2. Ξ_τ^i and $\Xi_{c_\tau}^i$ are defined in Appendix F, respectively.

Proof. See Appendix F. ■

In (19a) we recognize J_{cen} as the standard LQG cost (fully connected graph with no delays). Further, there are two intuitive interpretations for Theorem 16 that are represented in Fig. 9 for a 3-agents system. The intermediate graph topologies are different, but the starting and ending topologies are equal for both. Along the upper path, $J_{\text{dec}} - J_{\text{cen}}$ is the additional cost incurred due to decentralization alone, and $J_{\text{dec,del}} - J_{\text{dec}}$ is the further additional cost due to delays. Likewise, along the lower path, $J_{\text{del}} - J_{\text{cen}}$ is the additional cost due to delays alone and $J_{\text{dec,del}} - J_{\text{del}}$ is the further additional cost due to decentralization. Finally, J_Q is the additional cost incurred due to suboptimality. Theorem 16 unifies existing cost decomposition results for the centralized [33, §14.6], decentralized [15, Thm. 16], and delayed [19, Prop. 6] cases.

Remark 17 *Delay and decentralization do not contribute independently to the cost. Specifically, the marginal increase in cost due to adding processing delays depends on the graph topology. Likewise, the marginal increase in cost due to removing communication links depends on the processing delay. In other words, $J_{\text{cen}} + J_{\text{dec,del}} \neq J_{\text{dec}} + J_{\text{del}}$.*

Remark 18 *There is a dual expression for the cost J_{cen} in (19a):*

$$J_{\text{cen}} = \text{tr}(X_{\text{cen}} B_1 B_1^\top) + \text{tr}(Y_{\text{cen}} F_{\text{cen}}^\top D_{12}^\top D_{12} F_{\text{cen}}).$$

Fig. 8: The average optimal cost, as a function of processing delay, for the 4-agent system of Fig. 7 with different network topologies. For each topology, the cost is an increasing function of the processing delay.

Fig. 9: The optimal cost is interpreted using a 3-agent example. Additional cost is incurred either by removing links (decentralization) or by adding processing delays (red links).

The corresponding dual expressions for (19b)–(19d) are unfortunately more complicated. See Appendix F for details.

5.1 Synchronization example

We demonstrate Theorem 16 via a simple structured LQR example. We consider $N = 4$ identical lightly damped oscillators, with noiseless dynamics defined in Fig. 7 and no measurement noise. The oscillators begin with different initial conditions and the goal is to achieve synchronization.

The oscillators have identical dynamics defined by the differential equations in Fig. 7. The generators start at different positions. Fig. 7 depicts the synchronization of the position states of the four generators over time, when they communicate via the given diamond network and no processing delays.

In Fig. 8, we use the same system as in Fig. 7, but we plot the total average cost as a function of time delay for various network topologies. The highest cost corresponds to a fully disconnected network, while the lowest cost corresponds to a fully connected network. In the limit as $\tau \rightarrow \infty$ (infinite processing delay), the cost tends to the fully disconnected cost.

6 Conclusion

We studied a structured optimal control problem where multiple dynamically decoupled agents communicate over a delay network. Specifically, we characterized the structure and efficient implementation of optimal controllers at the individual agent level. We now propose some possible future applications for our work.

First, our approach can be readily generalized to treat cases with a combination of processing delays and network latency, where the various delays are heterogeneous but known. Next, the observer-regulator architecture elucidated in Fig. 6 could also be used to develop heuristics for solving cooperative control problems where the agents' dynamics are nonlinear or the noise distributions are non-Gaussian. Examples could include decentralized versions of the Extended Kalman Filter (EKF) or Unscented Kalman Filter (UKF). Finally, our closed-form expressions for the optimal cost can serve as lower bounds to the cost of practical implementation that have additional memory, power, or bandwidth limitations.

Appendices

A Definition of the Γ function

The Γ function takes in a four-block plant \mathcal{P} and adobe delay matrix Λ_m^i and returns a transformed plant $\tilde{\mathcal{P}}$ and FIR systems Π_u, Π_b . As in [19], we first consider the special case where $D_{12}^\top D_{12} = I$. The completion operator $\pi_\tau\{\cdot\}$ acts on a rational LTI system delayed by τ and returns the unique FIR system supported on $[0, \tau]$ that provides a rational completion:

$$\pi_\tau \left\{ \left[\begin{array}{c|c} A & B \\ \hline C & 0 \end{array} \right] e^{-s\tau} \right\} := \left[\begin{array}{c|c} A & e^{-A\tau}B \\ \hline C & 0 \end{array} \right] - \left[\begin{array}{c|c} A & B \\ \hline C & 0 \end{array} \right] e^{-s\tau}.$$

The input matrices B_2 and D_{12} of \mathcal{P} are partitioned according to the blocks of adobe delay matrix Λ_m^i . So, $B_2 = [B_{2_0} \ B_{2_\tau}]$, where the two blocks correspond to inputs with delay 0 and τ , respectively. D_{12} is partitioned in a similar manner. Define the Hamiltonian matrix

$$H = \begin{bmatrix} H_{11} & H_{12} \\ H_{21} & H_{22} \end{bmatrix} := \begin{bmatrix} A - B_{2_0} D_{12_0}^\top C_1 & -B_{2_0} B_{2_0}^\top \\ -C_1^\top P_\tau C_1 & -A^\top + C_1^\top D_{12_0} B_{2_0}^\top \end{bmatrix},$$

where $P_0 := D_{12_0} D_{12_0}^\top$ and $P_\tau := I - P_0$, and define its matrix exponential as $\Sigma := e^{H\tau}$. Define the modified matrices

$$\begin{aligned} \tilde{B}_2 &:= [B_{2_0} \ \Sigma_{12}^\top C_1^\top D_{12_\tau} + \Sigma_{22}^\top B_{2_\tau}] \\ \tilde{C}_1 &:= (P_\tau C_1 + P_0 C_1 \Sigma_{22}^\top - D_{12_0} B_{2_0}^\top \Sigma_{21}^\top) \Sigma_{22}^{-\top}, \end{aligned}$$

where the Σ_{ij} are partitioned the same way as the H_{ij} . The modified four-block plant output by Γ is then

$$\tilde{\mathcal{P}} := \begin{bmatrix} \tilde{\mathcal{P}}_{11} & \tilde{\mathcal{P}}_{12} \\ \mathcal{P}_{21} & \mathcal{P}_{22} \end{bmatrix} := \left[\begin{array}{c|cc} A & B_1 & \tilde{B}_2 \\ \hline \tilde{C}_1 & 0 & D_{12} \\ C_2 & D_{21} & 0 \end{array} \right],$$

Finally, define the FIR systems

$$\begin{bmatrix} \tilde{\Pi}_u \\ \tilde{\Pi}_b \end{bmatrix} := \pi_\tau \left\{ \left[\begin{array}{cc|c} H_{11} & H_{12} & B_{2\tau} \\ H_{21} & H_{22} & -C_1^\top D_{12\tau} \\ \hline D_{12_0}^\top C_1 & B_{2_0} & 0 \\ C_2 & 0 & 0 \end{array} \right] e^{-s\tau} \right\}.$$

FIR outputs of Γ are $\Pi_u := \begin{bmatrix} I & \tilde{\Pi}_u \\ 0 & I \end{bmatrix}$ and $\Pi_b := [0 \quad \tilde{\Pi}_b]$.

In the general case $D_{12}^\top D_{12} \neq I$, we can use a standard change of variables to transform back to the case $D_{12}^\top D_{12} = I$. See [17, Rem. 2] for details.

B Gramian equations

Here we provide the set of Lyapunov equations that are uniquely associated with the multi-agent problem.

Lemma 19 *Suppose $(X_{\text{cen}}, F_{\text{cen}})$ and (X^i, F^i) are defined in (7a) and (9a) respectively. Then $W_X^i := X^i - X_{\text{cen}_{ii}} \succeq 0$ is the unique solution to the Lyapunov equation*

$$(A_{ii} + B_{2_{ii}} F^i)^\top W_X^i + W_X^i (A_{ii} + B_{2_{ii}} F^i) + (E_{m_i} F^i - F_{\text{cen}} E_{n_i})^\top D_{12}^\top D_{12} (E_{m_i} F^i - F_{\text{cen}} E_{n_i}) = 0. \quad (21)$$

Proof. Left and right multiply the ARE for (7a) by $E_{n_i}^\top$ and E_{n_i} respectively, and subtract it from (9a). The result follows from algebraic manipulation and applying the definitions of F^i and F_{cen} . Since the final term in (21) is positive semidefinite and $A_{ii} + B_{2_{ii}} F^i$ is Hurwitz, it follows that $W_X^i := X^i - X_{\text{cen}_{ii}} \succeq 0$ and is unique. ■

We also have a dual analog to Lemma 19, provided below.

Lemma 20 *Consider the setting of Lemma 19. There exists a unique $W_Y^i \succeq 0$ that satisfies the Lyapunov equation*

$$(A_{ii} + B_{2_{ii}} F^i) W_Y^i + W_Y^i (A_{ii} + B_{2_{ii}} F^i)^\top + E_{n_i}^\top \bar{L} \bar{\mathbf{I}}_p D_{21} D_{21}^\top \bar{\mathbf{I}}_p^\top \bar{L}^\top E_{n_i} = 0. \quad (22)$$

Proof. Since $E_{n_i}^\top \bar{L} \bar{\mathbf{I}}_p D_{21} D_{21}^\top \bar{\mathbf{I}}_p^\top \bar{L}^\top E_{n_i} \succeq 0$ and the matrix $A_{ii} + B_{2_{ii}} F^i$ is Hurwitz, $W_Y^i \succeq 0$ and is unique. ■

C Proof of Theorem 7

For the case $\tau = 0$, the optimization problem (13) is a least squares problem with a subspace constraint, so the necessary and sufficient conditions for optimality are given by the normal equations $\mathcal{T}_{12}^\sim (\mathcal{T}_{11} + \mathcal{T}_{12} \mathcal{Q} \mathcal{T}_{21}) \mathcal{T}_{21}^\sim \in (\mathcal{H}_2 \cap \mathcal{S}_0)^\perp$ with the constraint that $\mathcal{Q} \in \mathcal{H}_2 \cap \mathcal{S}_0$.

We can check membership $\mathcal{F} \in (\mathcal{H}_2 \cap \mathcal{S}_0)^\perp$ by checking if $\mathcal{F}_{ij} \in \mathcal{H}_2^\perp$ whenever there is a path $j \rightarrow i$. For example, consider the two-node graph $1 \rightarrow 2$. Then we have

$$\mathcal{H}_2 \cap \mathcal{S}_0 = \begin{bmatrix} \mathcal{H}_2 & 0 \\ \mathcal{H}_2 & \mathcal{H}_2 \end{bmatrix} \quad \text{and} \quad (\mathcal{H}_2 \cap \mathcal{S}_0)^\perp = \begin{bmatrix} \mathcal{H}_2^\perp & \mathcal{L}_2 \\ \mathcal{H}_2^\perp & \mathcal{H}_2^\perp \end{bmatrix}.$$

So here, $\mathcal{F} \in (\mathcal{H}_2 \cap \mathcal{S}_0)^\perp$ if and only if $\mathcal{F}_{11}, \mathcal{F}_{21}, \mathcal{F}_{22} \in \mathcal{H}_2^\perp$. We will show that the proposed \mathcal{Q}_{opt} in (15) is optimal by directly verifying the normal equations.

Substituting \mathcal{Q}_{opt} from (15) into $\mathcal{T}_{11} + \mathcal{T}_{12}\mathcal{Q}_{\text{opt}}\mathcal{T}_{21}$ with \mathcal{T}_{ij} defined in (14) and simplifying, we obtain the closed-loop map

$$\mathcal{T}_{11} + \mathcal{T}_{12}\mathcal{Q}_{\text{opt}}\mathcal{T}_{21} = \left[\begin{array}{c|c} A_{\text{cl}} & B_{\text{cl}} \\ \hline C_{\text{cl}} & 0 \end{array} \right] := \left[\begin{array}{cc|c} \bar{A} + \bar{B}\bar{F} & -\bar{L}\bar{C}\bar{\mathbf{1}}_n & -\bar{L}\bar{\mathbf{1}}_p D_{21} \\ 0 & A + LC_2 & B_1 + LD_{21} \\ \hline C_1 \bar{\mathbf{1}}_n^\top + D_{12} \bar{\mathbf{1}}_m^\top \bar{F} & C_1 & 0 \end{array} \right]. \quad (23)$$

Next, we show that the controllability Gramian for the closed loop map is block-diagonal.

Lemma 21 *The controllability Gramian for the closed-loop map (23) is given by*

$$\Theta := \text{blkd}(\{E_{n_i} W_Y^i E_{n_i}^\top\}_{i \in [N]}, Y_{\text{cen}}),$$

where Y_{cen} and W_Y^i are defined in Eq. (7b) and Lemma 20, respectively. In other words, $\Theta \succeq 0$ is the unique solution to $A_{\text{cl}}\Theta + \Theta A_{\text{cl}}^\top + B_{\text{cl}}B_{\text{cl}}^\top = 0$.

Proof. A_{cl} is Hurwitz and $B_{\text{cl}}B_{\text{cl}}^\top \succeq 0$ so the Lyapunov equation has a unique solution and $\Theta \succeq 0$. We can verify the solution by direct substitution using Lemma 20 and the ARE associated with (7b). \blacksquare

Lemma 21 has the following statistical interpretation. If the controlled system (23) is driven by standard Gaussian noise, its state in these coordinates will have a steady-state covariance Θ , so each block component will be mutually independent.

Proof of optimality Let $\Omega := \mathcal{T}_{12}^\sim(\mathcal{T}_{11} + \mathcal{T}_{12}\mathcal{Q}_{\text{opt}}\mathcal{T}_{21})\mathcal{T}_{21}^\sim$. Substituting \mathcal{Q}_{opt} from (15) and using (23), we obtain

$$\Omega = \left[\begin{array}{ccc|c} -A_K^\top & -C_K^\top C_{\text{cl}} & 0 & 0 \\ 0 & A_{\text{cl}} & B_{\text{cl}}B_L^\top & B_{\text{cl}}D_{21}^\top \\ 0 & 0 & -A_L^\top & -C_2^\top \\ \hline B_2^\top & D_{12}^\top C_{\text{cl}} & 0 & 0 \end{array} \right], \quad (24)$$

where we defined $A_K := A + B_2 F_d$, $C_K := C_1 + D_{12} F_d$, $A_L := A + LC_2$, $B_L := B_1 + LD_{21}$, and $A_{\text{cl}}, B_{\text{cl}}, C_{\text{cl}}$, are defined in (23). Apply the state transformation

$$T = \begin{bmatrix} I & [\bar{\mathbf{1}}_n^\top \bar{X} & 0] & \bar{\mathbf{1}}_n^\top \bar{X} \bar{W} \bar{\mathbf{1}}_p \\ 0 & I & \Theta \bar{\mathbf{1}}_p \\ 0 & 0 & I \end{bmatrix},$$

where we defined $\bar{W} := \text{blkd}(\{E_{n_i} W_X^i E_{n_i}^\top\}_{i \in [N]})$ and $\bar{X} := \text{blkd}(\{E_{n_i} W_X^i E_{n_i}^\top + X_{\text{cen}}\}_{i \in [N]})$, and Θ is defined in Lemma 21. Simplify using Riccati and Lyapunov equations from Section 2.2 and Appendix B respectively, we find that the mode $A + LC_2$ is uncontrollable. Removing it, we obtain

$$\Omega = \left[\begin{array}{ccc|c} -A_K^\top & \star_1 & \star & \star \\ 0 & \bar{A} + \bar{B}\bar{F} & \star_2 & \star_3 \\ 0 & 0 & -A_L^\top & -C_2^\top \\ \hline B_2^\top & \star_4 & \star & 0 \end{array} \right]. \quad (25)$$

where we have defined the symbols

$$\begin{aligned}
\star_1 &:= -A_K^\top \bar{\mathbf{1}}_n^\top \bar{X} - C_K^\top (C_1 \bar{\mathbf{1}}_n^\top + D_{12} \bar{\mathbf{1}}_m^\top \bar{F}) - \bar{\mathbf{1}}_n^\top \bar{X} (\bar{A} + \bar{B} \bar{F}) \\
\star_2 &:= -\bar{L} \bar{\mathbf{1}}_p D_{21} B_L^\top - \bar{L} \bar{C} \bar{\mathbf{1}}_n Y_{\text{cen}} + (\bar{A} + \bar{B} \bar{F}) \bar{W} \bar{\mathbf{1}}_p + \bar{W} \bar{\mathbf{1}}_p A_L^\top \\
\star_3 &:= -\bar{L} \bar{\mathbf{1}}_p D_{21}^\top + \bar{W} \bar{\mathbf{1}}_p C_2^\top \\
\star_4 &:= D_{12}^\top (C_1 \bar{\mathbf{1}}_n^\top + D_{12} \bar{\mathbf{1}}_m^\top \bar{F}) + B_2^\top \bar{\mathbf{1}}_n^\top \bar{X}.
\end{aligned}$$

Now consider a block Ω_{ij} for which there is a path $j \rightarrow i$.

$$\Omega_{ij} = \left[\begin{array}{ccc|c} -A_{Kii}^\top & \star_{1i} & \star & \star \\ 0 & \bar{A} + \bar{B} \bar{F} & \star_{2:j} & \star_{3:j} \\ 0 & 0 & -A_{Ljj}^\top & -C_{2jj}^\top \\ \hline B_{2ii}^\top & \star_{4i} & \star & 0 \end{array} \right]. \quad (26)$$

Let \star_1^k and \star_4^k denote the k^{th} block column and let \star_2^k and \star_3^k denote the k^{th} block row. Algebraic manipulation reveals that

- (i) If $i \in \underline{k}$ and $\ell \in \underline{k}$, then $\star_{1i\ell}^k = \star_{4i\ell}^k = 0$.
- (ii) If $\ell \notin \underline{k}$ or $j \notin \underline{k}$, then $\star_{2\ell j}^k = \star_{3\ell j}^k = 0$.

Consider the k^{th} diagonal block of $\bar{A} + \bar{B} \bar{F}$ in (26), which is $A + E_{n_{\underline{k}}} B_{2_{\underline{k}\underline{k}}} F^k E_{n_{\underline{k}}}^\top$. This block is itself block-diagonal; it contains the block $A_{\underline{k}\underline{k}} + B_{2_{\underline{k}\underline{k}}} F^k$ and smaller blocks $A_{\ell\ell}$ for all $\ell \notin \underline{k}$. We have three cases.

1. If $k \in \bar{i}$, then for all $\ell \in \underline{k}$, we have $\star_{1i\ell}^k = \star_{4i\ell}^k = 0$ from Item (i) above, so the mode $A_{\underline{k}\underline{k}} + B_{2_{\underline{k}\underline{k}}} F^k$ is unobservable.
2. If $k \in \bar{i}$, but instead $\ell \notin \underline{k}$, we have $\star_{2\ell j}^k = \star_{3\ell j}^k = 0$ from Item (ii) above, so the modes $A_{\ell\ell}$ are uncontrollable.
3. If $k \notin \bar{i}$, then $k \notin \bar{j}$ because $j \rightarrow i$ by assumption. Then from Item (ii) above, all such modes are uncontrollable.

Consequently every block of $\bar{A} + \bar{B} \bar{F}$ is either uncontrollable or unobservable, leading us to the reduced realization

$$\Omega_{ij} = \left[\begin{array}{cc|c} -A_{Kii}^\top & \star & \star \\ 0 & -A_{Ljj}^\top & -C_{2jj}^\top \\ \hline B_{2ii}^\top & \star & 0 \end{array} \right]. \quad (27)$$

Therefore, $\Omega_{ij} \in \mathcal{H}_2^\perp$ whenever $j \rightarrow i$, as required.

D Proof of Theorem 11

Start with the convexified optimization problem (13). Based on the structured realization (14), we see that \mathcal{T}_{21} is block-diagonal. Therefore, the optimal cost can be split by columns:

$$\|\mathcal{T}_{11} + \mathcal{T}_{12} \mathcal{Q} \mathcal{T}_{21}\|_2^2 = \sum_{i=1}^N \|\mathcal{T}_{11:i} + \mathcal{T}_{12:i} \mathcal{Q}_{ii} \mathcal{T}_{21:ii}\|_2^2.$$

Since $\mathcal{Q} \in \mathcal{H}_2 \cap \mathcal{S}_\tau$, we can factor each block column of \mathcal{Q} as $\mathcal{Q}_{ii} = \Lambda_m^i \tilde{\mathcal{Q}}_{ii}$, where $\tilde{\mathcal{Q}}_{ii} \in \mathcal{H}_2$ has no structure or delay, and Λ_m^i is the adobe delay matrix (defined in Section 2.1). We can therefore optimize for each block column $\tilde{\mathcal{Q}}_{ii}$ separately. Thus, each subproblem is to

$$\underset{\tilde{\mathcal{Q}}_{ii} \in \mathcal{H}_2}{\text{minimize}} \quad \|\mathcal{T}_{11:i} + \mathcal{T}_{12:i} \Lambda_m^i \tilde{\mathcal{Q}}_{ii} \mathcal{T}_{21:ii}\|_2^2, \quad (28)$$

Define $\mathcal{T}_i := \begin{bmatrix} \mathcal{T}_{11:i} & \mathcal{T}_{12:i} \\ \mathcal{T}_{21:ii} & 0 \end{bmatrix}$. Comparing to (13)–(14), we observe that (28) is a special case of the problem (13), subject to the transformations $\mathcal{P} \mapsto \mathcal{P}_i$ (defined in (8)) and $F_d \mapsto F_{d_{ii}}$, $L_d \mapsto E_{n_i}^\top E_{n_i} L^i$, and $\mathcal{Q} \mapsto \Lambda_m^i \tilde{\mathcal{Q}}_{ii}$. If we define the associated \mathcal{J}_i for this subproblem (according to (11)), we view the subproblem as that of finding the \mathcal{H}_2 -optimal controller for the plant \mathcal{P}_i subject to an adobe input delay, as illustrated in the left panel of Fig. 10. The key difference between this problem and (6) is that we no longer have a sparsity constraint.

Fig. 10: Equivalent subproblems via commuting Λ_m^i and \mathcal{J}_i . Dimensions of signals are indicated along the arrows.

The adobe delay Λ_m^i can be shifted to the input channel, shown in the right panel of Fig. 10. This follows from leveraging state-space properties and the block structure of certain blocks of \mathcal{J}_i . Examples include $B_{2_{ii}} \Lambda_m^i = \Lambda_m^i B_{2_{ii}}$ and $\Lambda_m^i E_{n_i}^\top E_{n_i} L^i = E_{n_i}^\top E_{n_i} L^i$.

The remainder of the proof proceeds as follows: we define \mathcal{K}^i to be the shaded system in Fig. 10 (right panel). This is a standard adobe delayed problem, so we can apply the Γ transformation illustrated in Fig. 2. Specifically, we define $(\tilde{\mathcal{P}}_i, \Pi_{u_i}, \Pi_{b_i}) = \Gamma(\mathcal{P}_i, \Lambda_m^i)$, and obtain Fig. 11.

Fig. 11: Transformation of the right panel of Fig. 10 using the loop-shifting transformation illustrated in Fig. 2.

By the properties of the loop-shifting transformation discussed in Section 2.1, the optimal \tilde{K}^i is found by solving a standard non-delayed LQG problem in the (rational) plant $\tilde{\mathcal{P}}_i$, whose solution

is

$$\tilde{\mathcal{K}}_i = \left[\begin{array}{c|c} \frac{A_{ii} + \tilde{B}_{2ii}\tilde{F}^i + E_{n_i}^\top E_{n_i} L^i C_{2ii}}{\tilde{F}^i} & -E_{n_i}^\top E_{n_i} L^i \\ \hline & 0 \end{array} \right].$$

Inverting each transformation, $\mathcal{K}_i = \Pi_{u_i} \tilde{\mathcal{K}}_i (I - \Pi_{b_i} \tilde{\mathcal{K}}_i)^{-1}$, and we can recover the Youla parameter via $\tilde{\mathcal{Q}}_{ii} = \mathcal{F}_u(\mathcal{J}_i^{-1}, \mathcal{K}_i)$, which leads to (29). Now zero-pad, reintroduce delays, and concatenate,

$$\tilde{\mathcal{Q}}_{ii} = \left[\begin{array}{cc|c} A_{ii} & B_{2ii} \Pi_{u_i} \tilde{F}^i & -E_{n_i}^\top E_{n_i} L^i \\ -E_{n_i}^\top E_{n_i} L^i C_{2ii} & A_{ii} + \tilde{B}_{2ii} \tilde{F}^i - E_{n_i}^\top E_{n_i} L^i \Pi_{b_i} \tilde{F}^i + E_{n_i}^\top E_{n_i} L^i C_{2ii} & -E_{n_i}^\top E_{n_i} L^i \\ \hline -F_{d_{ii}} & \Pi_{u_i} \tilde{F}^i & 0 \end{array} \right]. \quad (29)$$

to obtain the global Youla parameter (17) via $\mathcal{Q}_{\text{opt}} = \sum_{i=1}^N E_{m_i} \Lambda_m^i \tilde{\mathcal{Q}}_{ii} E_{p_i}^\top$ and recover the optimal controller (18) via $\mathcal{K}_{\text{opt}} = \mathcal{F}_l(\mathcal{J}, \mathcal{Q}_{\text{opt}})$.

E Proof of Theorem 12

From Lemma 2, the set of sub-optimal controllers is parameterized as $\mathcal{K} = \mathcal{F}_l(\mathcal{J}, \mathcal{Q})$, where $\mathcal{Q} \in \mathcal{S}_\tau$. Equivalently, write $\mathcal{K} = \mathcal{F}_l(\mathcal{J}, \mathcal{Q}_{\text{opt}} + \mathcal{Q}_\Delta)$, where $\mathcal{Q}_\Delta \in \mathcal{S}_\tau$ and \mathcal{Q}_{opt} is given in Theorem 11. The controller equation $u = \mathcal{K}y$ can be expanded using the LFT as $\begin{pmatrix} u \\ \eta \end{pmatrix} = \mathcal{J} \begin{pmatrix} y \\ v \end{pmatrix}$ with $v = \mathcal{Q}\eta$. If \mathcal{J} has state ξ , the state-space equation for \mathcal{J} decouples as

$$\begin{aligned} \dot{\xi}_i &= (A_{ii} + B_{2ii}F_{d_{ii}} + L^i C_{2ii})\xi_i - L^i y_i + B_{2ii} v_i, \\ u_i &= F_{d_{ii}} \xi_i + v_i, \\ \eta_i &= -C_{2ii} \xi_i + y_i, \quad \text{for } i = 1, \dots, N. \end{aligned}$$

Note that we replaced $L_{d_{ii}}$ by L^i from (9b). This leads to simpler algebra, but is in principle not required. Meanwhile, the \mathcal{Q} equation is coupled: $v = (\mathcal{Q}_{\text{opt}} + \mathcal{Q}_\Delta)\eta$. Now consider Agent i . Since we are interested in the agent-level implementation, we begin by extracting u_i , which requires finding v_i . Separate \mathcal{Q} by columns as in Appendix D to obtain

$$\begin{aligned} v_i &= E_{m_i}^\top (\mathcal{Q}_{\text{opt}} + \mathcal{Q}_\Delta) \eta \\ &= \sum_{k \in [N]} E_{m_i}^\top E_{m_k} \Lambda_m^k \left(\tilde{\mathcal{Q}}_{kk} + \hat{\mathcal{Q}}_{kk} \right) \eta_k \\ &= \left(\tilde{\mathcal{Q}}_{ii} + \hat{\mathcal{Q}}_{ii} \right) \eta_i + e^{-s\tau} \sum_{k \in \bar{i}} \left(\tilde{\mathcal{Q}}_{ik} + \hat{\mathcal{Q}}_{ik} \right) \eta_k, \end{aligned} \quad (30)$$

where $\tilde{\mathcal{Q}}_{ii}$ is given in (29), and $\hat{\mathcal{Q}} \in \mathcal{S}_0$ is the delay-free component of \mathcal{Q}_Δ . A possible distributed implementation is to have Agent i simulate ξ_i locally. Since y_i is available locally, then so is η_i . We further suppose Agent i computes $v_{i,\underline{i}} := (\tilde{\mathcal{Q}}_{ii} + \hat{\mathcal{Q}}_{ii})\eta_i$ locally. Component $v_{i,i}$ is used locally, while component $v_{i,j}$ for $j \in \underline{i}$ is transmitted to descendant j . Each agent then computes v_i by summing its local $v_{i,i}$ with the delayed $e^{-s\tau} v_{i,k}$ received from strict ancestors $k \in \bar{i}$. The complete agent-level implementation is shown in Fig. 3.

When $\hat{Q} = 0$, we recover the optimal controller. In this case, the equations simplify considerably; standard state-space manipulations reduce Fig. 3 to the simpler Fig. 4. It is worth noting that the optimal controller does not depend on the choice of nominal gain F_d .

F Proof of Theorem 16

All the estimation, control gains and Riccati solutions used here are defined in Section 2.2. The additional cost incurred due to sub-optimality is $J_Q := \|\mathcal{T}_{12}\mathcal{Q}_\Delta\mathcal{T}_{21}\|_2^2$ [33, §14.6]. Using [33, Lem. 14.3], we have $J_Q := \|\mathcal{T}_{12}\mathcal{Q}_\Delta D_{21}\|_2^2$.

J_{cen} (19a) The optimal cost for a fully connected graph [33, Thm. 14.7] is

$$\begin{aligned} J_{\text{cen}} &:= \left\| \left[\begin{array}{c|c} A + B_2 F_{\text{cen}} & B_1 \\ \hline C_1 + D_{12} F_{\text{cen}} & 0 \end{array} \right] \right\|_2^2 + \left\| \left[\begin{array}{c|c} A_L & B_L \\ \hline D_{12} F_{\text{cen}} & 0 \end{array} \right] \right\|_2^2, \\ &= \text{tr}(Y_{\text{cen}} C_1^\top C_1) + \text{tr}(X_{\text{cen}} L D_{21} D_{21}^\top L^\top), \\ &= \text{tr}(X_{\text{cen}} B_1 B_1^\top) + \text{tr}(Y_{\text{cen}} F_{\text{cen}}^\top D_{12}^\top D_{12} F_{\text{cen}}), \end{aligned}$$

where A_L, B_L are defined in Appendix C for (24).

J_{dec} (19b) Consider that \mathcal{K}_{opt} in (16) is a sub-optimal centralized controller for $\|\mathcal{T}_{11} + \mathcal{T}_{12}\mathcal{Q}\mathcal{T}_{21}\|_2^2$, subject to $\mathcal{Q} \in \mathcal{H}_2$. Centralized \mathcal{H}_2 theory [33] implies that $J_{\text{dec}} = J_{\text{cen}} + \Delta$, where $\Delta := \|D_{12}\mathcal{Q}_{\text{you}}D_{21}\|_2^2$ and \mathcal{Q}_{you} is the centralized Youla parameter. Here, $\mathcal{Q}_{\text{you}} = \mathcal{F}_u(\mathcal{J}^{-1}, \mathcal{K}_{\text{opt}})$, where

$$\mathcal{J}^{-1} = \left[\begin{array}{c|cc} A & B_2 & -L \\ \hline C_2 & 0 & I \\ -F_{\text{cen}} & I & 0 \end{array} \right].$$

After simplifications, we obtain

$$\mathcal{Q}_{\text{you}} = \left[\begin{array}{c|c} \bar{A} + \bar{B}\bar{F} & -\bar{L}\bar{\mathbf{1}}_p \\ \hline \bar{\mathbf{1}}_m^\top(\bar{F} - \bar{F}_{\text{cen}}) & 0 \end{array} \right].$$

We substitute \mathcal{Q}_{you} into the expression for Δ , using $\|D_s + C_s(sI - A_s)^{-1}B_s\|_2^2 = \text{tr}(C_s W_c C_s^\top)$, where W_c is the controllability Gramian given by Lyapunov equation $A_s W_c + W_c A_s^\top + B_s B_s^\top = 0$. Based on the Lemma 19 and using the identity $L_i = E_{n_i} L^i E_{p_i}^\top$, we evaluate

$$\begin{aligned} \Delta &= \sum_{i=1}^N \text{tr}(D_{21}^\top L_i^\top E_{n_i} \{X^i - X_{\text{cen}_{ii}}\} E_{n_i}^\top L_i D_{21}) \\ &= \text{tr}((\text{blkd}(\{X^i(1, 1)\}) - X_{\text{cen}}) L D_{21} D_{21}^\top L^\top). \end{aligned}$$

We obtain (19b) by substituting Δ into $J_{\text{dec}} = J_{\text{cen}} + \Delta$.

Alternative formulas for the cost We obtained an alternative formula for J_{cen} in Appendix F. Similarly in Appendix F for J_{dec} , $\|D_s + C_s(sI - A_s)^{-1}B_s\|_2^2$ is also equal to $\text{tr}(B_s B_s^\top W_o)$, where W_o is the observability Gramian given by the dual Lyapunov equation $A_s^\top W_o + W_o A_s + C_s^\top C_s = 0$. Based on Lemma 20, we can evaluate $\Delta = \sum_{i=1}^N \text{tr}(D_{12}(E_{m_i} F_i - F_{\text{cen}} E_{n_i}) W_Y^i (E_{m_i} F_i - F_{\text{cen}} E_{n_i})^\top D_{12}^\top)$. Similar alternative formulas exist for (19c), and (19d) as well.

$J_{\text{dec,del}}$ (19c) We can split the cost in (13) into a sum of N separate terms because \mathcal{T}_{21} is block-diagonal. Using [19, Prop. 6] on each of these N problems, we write $J_{\text{dec,del}}$ as a combination of a non-delayed cost J_{dec} and a Δ incurred by adding delays to that system: $J_{\text{dec,del}} = J_{\text{dec}} + \Delta$, where $\Delta := \sum_{i=1}^N \text{tr}(D_{21_{ii}}^\top L_i^\top E_{n_i}^\top (\Xi_\tau^i - X^i) E_{n_i} L_i D_{21_{ii}})$. Also, $\Delta = \text{tr}(\text{blkd}(\{\Xi_\tau^i(1,1) - X^i(1,1)\}) L D_{21} D_{21}^\top L^\top)$ since $L_i = E_{n_i} L_i^\top E_{p_i}^\top$. We obtain (19c) by substituting Δ into $J_{\text{dec,del}} = J_{\text{dec}} + \Delta$. See Appendix F below for explanation on Ξ_τ^i .

J_{del} (19d) Derivation is analogous to that of $J_{\text{dec,del}}$. See Appendix F below for explanation on $\Xi_{c_\tau}^i$.

Proofs for (20a) We have $X^i - X_{\text{cen}_{ii}} \succeq 0$ in Lemma 19 for all $i \in [N]$. The properties of a positive semi-definite matrix give us $X^i(1,1) - X_{\text{cen}_{ii}}(1,1) \succeq 0$, and hence $\text{blkd}(\{X_{\text{cen}}(i,i)\}) \preceq X_{\text{dec}}$.

Now we define Ξ_τ^i and establish that $\Xi_\tau^i - X^i \succeq 0$. The Hamiltonian for the control Riccati equation (10) is

$$H^i := \begin{bmatrix} A_{ii} - \tilde{B}_{2_{ii}} M^{-1} D_{12_{ii}}^\top \tilde{C}_{1_{ii}} & -\tilde{B}_{2_{ii}} M^{-1} \tilde{B}_{2_{ii}}^\top \\ -\tilde{C}_{1_{ii}}^\top P_\tau \tilde{C}_{1_{ii}} & -A_{ii}^\top + \tilde{C}_{1_{ii}}^\top D_{12_{ii}} M^{-1 \top} \tilde{B}_{2_{ii}}^\top \end{bmatrix},$$

where $M := D_{12_{ii}}^\top D_{12_{ii}}$, $P_0 := D_{12_{ii}} M^{-1} D_{12_{ii}}^\top$ and $P_\tau := I - P_0$, and define the corresponding symplectic matrix exponential as $\Sigma^i := e^{H^i \tau}$. The elements $\Sigma_{22}^i, \Sigma_{21}^i$ of this modified Σ^i are used to define the Ξ_τ^i . For all $i \in [N]$, we define $\Xi_\tau^i := \tilde{X}^i - (\Sigma_{22}^i \Sigma_{21}^i)^\top$. By solving the associated Differential Riccati Equation (DRE) [19, Eq. 16], we show $\Xi_\tau^i - X^i \succeq 0$ [19, §4.3]. This gives us $X_{\text{dec}} \preceq X_{\text{dec,del}}$.

Proofs for (20b) Next we consider the case of a fully connected graph with delays. So Agent i 's feedback policy looks like $u_i = \mathcal{K}_{ii}(s)y_i + \sum_{j \in [N] \setminus i} e^{-s\tau} \mathcal{K}_{ij}(s)y_j$. Since we solve for \mathcal{Q} by solving for individual columns \mathcal{Q}_{ii} , we define the associated state transition matrix for each column as $A_{ii}^c := \text{blkd}(\{A_{ii}, A_{ii}\})$, where $\underline{i} = [N] \setminus i$. We define the corresponding $B_{1_{ii}}^c, B_{2_{ii}}^c, C_{1_{ii}}^c, D_{12_{ii}}^c, C_{2_{ii}}^c$, and $D_{21_{ii}}^c$ in a similar manner. We also define a centralized $\Xi_{c_\tau}^i := \tilde{X}_c^i - (\Sigma_{22_c}^{i-1} \Sigma_{21_c}^i)^\top$ for each Γ -modified plant

$$\tilde{\mathcal{P}}_i^c := \left[\begin{array}{c|cc} A_{ii}^c & B_{1_{ii}}^c & \tilde{B}_{2_{ii}}^c \\ \hline \tilde{C}_{1_{ii}}^c & 0 & D_{12_{ii}}^c \\ C_{2_{ii}}^c & D_{21_{ii}}^c & 0 \end{array} \right].$$

Each individual column \mathcal{Q}_{ii} has its own $\tilde{\mathcal{P}}_i^c$ as the associated adobe delay matrix is different. We have a corresponding control ARE $(\tilde{X}_c^i, \tilde{F}_c^i) := \text{Ric}(A_{ii}^c, \tilde{B}_{2_{ii}}^c, \tilde{C}_{1_{ii}}^c, D_{12_{ii}}^c)$. We solve DREs for each $\Xi_{c_\tau}^i$ as in [19, §V.C] to obtain $\Xi_{c_\tau}^i - X_{\text{cen}_{ii}}^c \succeq 0$ for all $i \in [N]$, where $X_{\text{cen}_{ii}}^c$ is a reshuffling of X_{cen} to mirror the ordering of $\underline{i} = \{i, [N] \setminus i\}$. This proves that $\text{blkd}(\{X_{\text{cen}}(i,i)\}) \preceq X_{\text{cen,del}}$ for all $i \in [N]$.

Lemma 22 proves that $X_{\text{cen,del}} \preceq X_{\text{dec,del}}$ for all $i \in [N]$.

Lemma 22 $\Xi_{c_\tau}^i$ and Ξ_τ^i are the solutions of the DREs for delayed fully connected and decentralized graphs respectively. Then, $W_{\Xi}^i := \Xi_\tau^i - \Xi_{c_{ii}}^i \succeq 0$, where $\Xi_{c_{ii}}^i := E_{n_i}^\top \Xi_{c_\tau}^i E_{n_i}$, and i corresponds to Ξ_τ^i .

Proof. The DREs for Ξ_τ^i , and $\Xi_{c_\tau}^i$ are subtracted to obtain the differential Lyapunov equation

$$\begin{aligned} \dot{\Xi}_{c_{ii}}^i - \dot{\Xi}_\tau^i &= (A_{ii} + B_{2_{ii}} F_{\Xi}^i)^\top W_{\Xi}^i + W_{\Xi}^i (A_{ii} + B_{2_{ii}} F_{\Xi}^i) \\ &\quad + (E_{m_i} F_{\Xi}^i - F_{\Xi_c}^i E_{n_i})^\top D_{12}^\top D_{12} (E_{m_i} F_{\Xi}^i - F_{\Xi_c}^i E_{n_i}), \end{aligned}$$

where $F_{\Xi}^i := -(D_{12,i}^\top D_{12,i})^{-1} (\Xi_\tau^i B_{2_{ii}} + C_{1,i}^\top D_{12,i})^\top$, and $F_{\Xi_c}^i := -(D_{12,i}^{c\top} D_{12,i}^c)^{-1} (\Xi_{c_\tau}^i B_{2_{ii}}^c + C_{1,i}^{c\top} D_{12,i}^c)^\top$. The rest is analogous to the proof of Lemma 19. Finally, we obtain $\Xi_\tau^i - \Xi_{c_{ii}}^i - X^i + X_{\text{cen}_{ii}} \succeq 0$. Using $X^i - X_{\text{cen}_{ii}} \succeq 0$ from Lemma 19, we obtain $\Xi_\tau^i - \Xi_{c_{ii}}^i \succeq 0$. ■
